1. Abstract

A sampling programme in southern Madagascar was conducted in order to explore for new high-Ti ilmenite deposits in geological environments similar to that of the high-Ti ilmenite deposits in beach sands of SW India. A total of 40 samples were collected over about 700km of coast line. Half of the samples were taken from coastal sediments proximal to a belt of high-grade metasediments, exposed in the eastern part of southern Madagascar, and which resembles the khondalite belt of Kerala State in SW India. The remaining samples were taken from mainly coastal sediments in the western part of southern Madagascar. The sediments represented by these samples come from a large, long-lived (>500my) sedimentary basin.

The results of the study show that:

- Nearly all samples adjacent to the Madagascar khondalites ('eastern Madagascar') contain a high proportion of ilmenite with elevated TiO_2 , and 5 samples have average TiO_2 in ilmenite between 60 and 64 wt. %.
- The distribution of TiO_2 in ilmenite grains is distinctly bimodal in most samples from eastern Madagascar, pointing to several sources of ilmenite in the sediments.
- In the high-Ti samples (average ilmenite $\text{TiO}_2 > 60$ wt. %), the distribution of TiO_2 in ilmenite is unimodal with narrow ranges in TiO_2 .
- Samples adjacent to the large sedimentary basin ('western Madagascar') have average ilmenite with TiO_2 in the range 51-55 wt. %. Some samples have strongly bimodal distribution of TiO_2 in ilmenite, and in at least one place the high-Ti ilmenite population points to a 'fossil' Ti-enhanced ilmenite deposit (sample 68).
- There is evidence that leaching of ilmenite is an ongoing process in at least one site around Fort Dauphin in eastern Madagascar (sample 55).
- Average ilmenite and garnet compositions in samples from the high-Ti samples are identical to those of samples with high-Ti ilmenite from India.
- The combination of geological information (maps etc) and garnet/ilmenite chemistry thus proves to be an efficient tool in outlining new high-grade ilmenite deposits world wide.

2. Introduction

Studies of high-Ti ilmenite deposits in SW India have suggested that their source rocks are found within the Kerala khondalite belt (Soman, 1985; Bernstein 2003, 2004). Khondalites comprise aluminium-rich rocks, usually metasediments, which have undergone granulite facies metamorphism. The term usually covers regions dominated by garnet, sillimanite, graphite, biotite ilmenite bearing schists, but the regions often also contain slivers of charnockites and mafic lithologies, such as two pyroxene metagabbros. A study by Bernstein (2004) further constrains the source rocks of the Indian high-Ti ilmenite deposits to be sillimanite-bearing, garnet-rich lithologies, whereas orthopyroxene-bearing lithologies are less likely to yield material to the deposits. With this knowledge, and in the search for global Ti-rich ilmenite deposits, it was decided to look for other occurrences of khondalite rocks within the 35°N and 35°S belt which have been identified as the climatic region being of particular interest with regard to recent leaching of ilmenite (e. g. Force, 1991). Palaeo-reconstruction of plateconfigurations (Fig. 1) shows that prior to the break-up of Gondwanaland, the belt of khondalites, presently exposed in southern India, stretched across Sri Lanka to the eastern side of India, and into Madagascar to the other side of India. After the location of the khondalite belt in Madagascar was identified, a sampling programme was designed in order to test the hypothesis of khondalites being a source of easily weathered ilmenite, and in order to delineate new potential high-Ti ilmenite sand deposits.

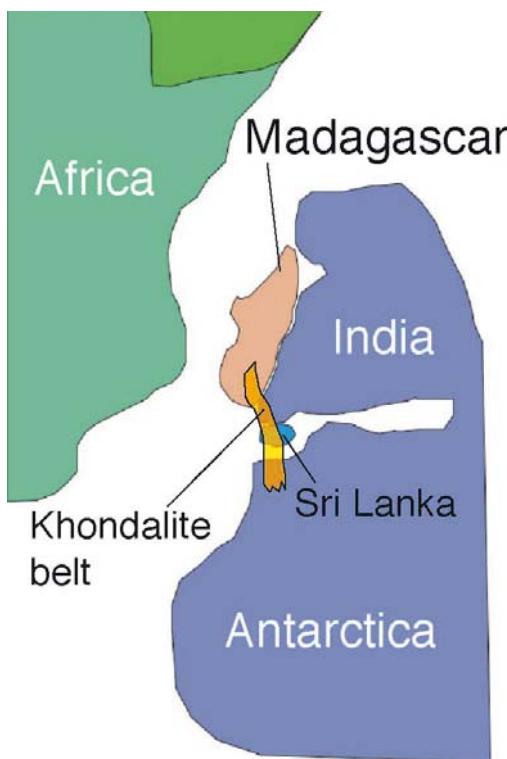

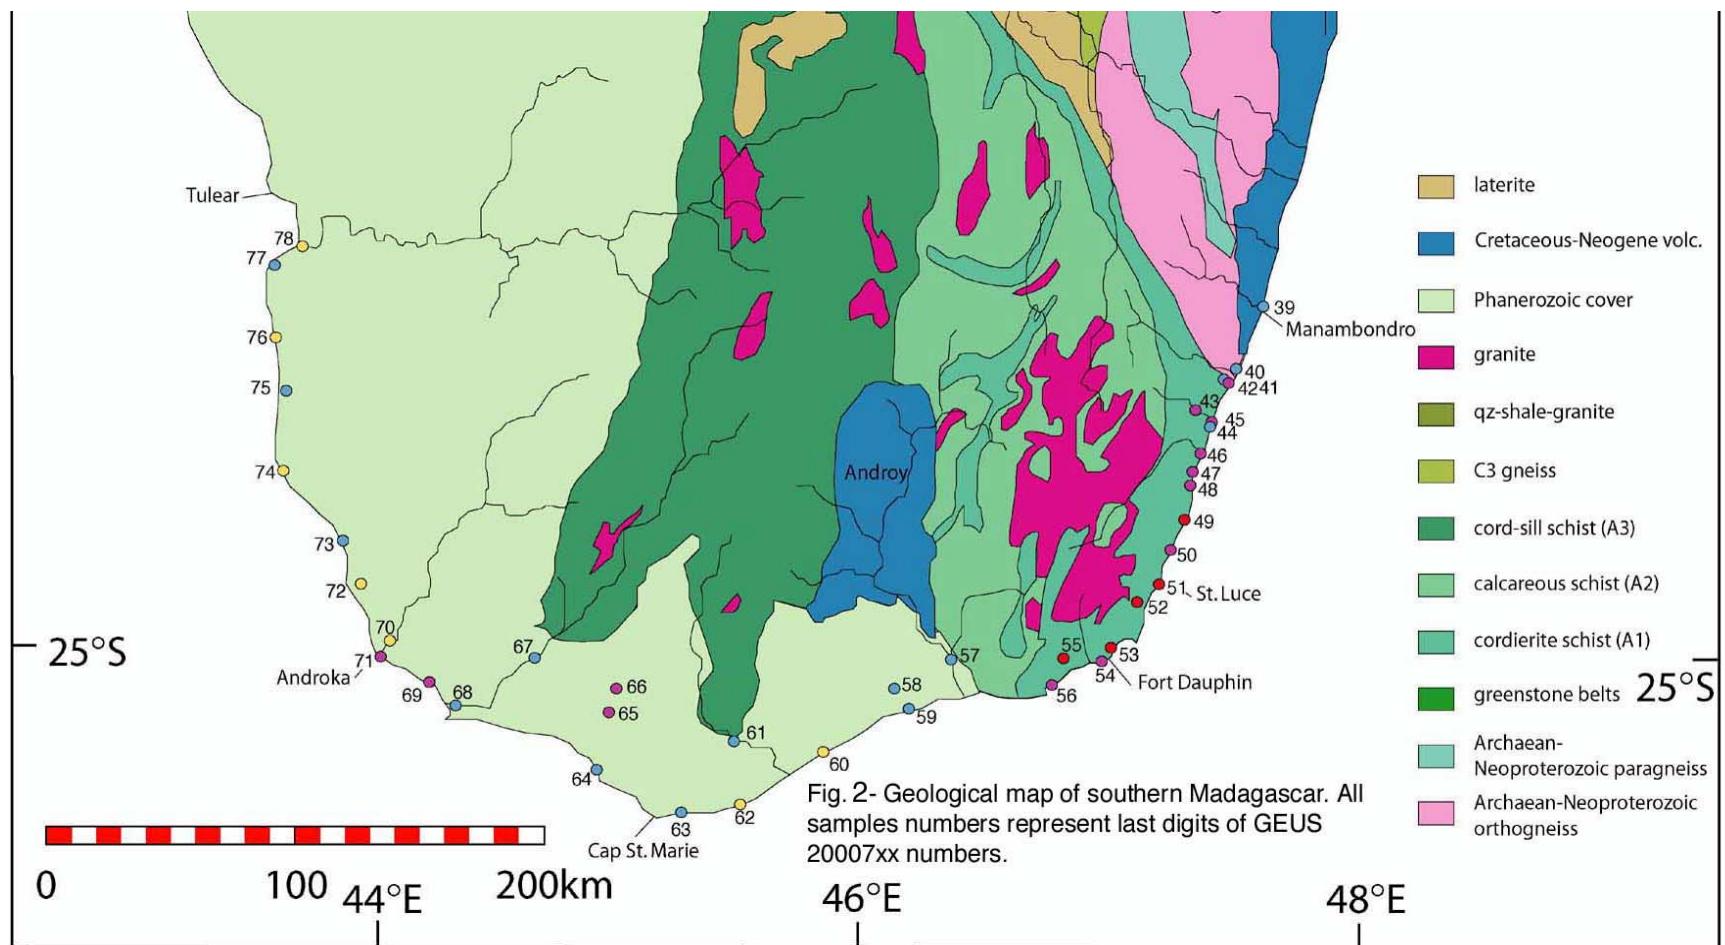

Figure 1. Reconstruction of palaeo-plates at ca. 140 Ma (after de Wit, 2003), showing the close association of Madagascar, India and Sri Lanka prior to continental break-up. The khondalite belt extends across all three continental fragments and into Antarctica.

3. Geological outline

The eastern part of southern Madagascar comprises a series of Precambrian basement rocks which underwent high-grade metamorphism during the late stages of the Panafrican orogeny (Fig. 2). Metamorphic ages are around 600 my, thus straddeling the Proterozoic-Palaeozoic boundary (de Wit, 2003). The gneisses were metamorphosed in upper amphibolite to granulite facies (Nicollet, 1990), and subsequently intruded by synorogenic granitoid bodies. The eastern edge of the island is rimmed by Mesozoic volcanic rocks, mainly basalts, erupted during the continental break-up that led to the separation of Madagascar from the Seychelles. In the central highlands of southern Madagascar is also found a large volcanic structure, Volcan de l'Androy, which is linked to the Mesozoic break-up in the presence of the Marion hot-spot (Storey et al., 1997). To the west, the basement rocks are covered by late Paleozoic to recent sedimentary rocks of terrestrial (oldest) and marine origin.

The lithologies of interest as source rocks for potential high-Ti ilmenite are the high-grade metamorphic paragneisses of southern Madagascar, and which are exposed as a >200km wide tract wedging out to the north and about 400 km in north-south dimension. The main interest concerns the cordierite schists (A1) as represented by the geological map (Besairie, 1965, and Fig. 2).

In order to evaluate the Ti potential of ilmenite from sediments around southern Madagascar, a sampling programme was initiated. The programme was conducted by consultant geologist Rasmus Christensen (see appendix 1). In about three weeks time Christensen collected a 0.5 kg sediment sample at about 20km spacing from Manambondro to about 50km west of Fort Dauphin, and at 40km spacing from 50km west of Fort Dauphin to Tulear on the west coast of southern Madagascar. The total length of coastline covered is about 700km, and a total of 40 samples were collected.

Figure 2.

4. Sample processing and analyses

All sediment samples were processed as follows: depending on the visual contents of heavy minerals, 30 to 90 grammes of sediment was split from the bulk, dried and washed on a 45 micrometer sieve. The fraction larger than 45 micrometer was then sieved through 710 micrometer screen and the fraction between 45 and 710 micrometer was passed through a centrifuge in CHBr₃ with a density of 2.8 gr/cc. The heavy mineral fraction was then mounted in epoxy, cut to a thickness of ca. 200 micrometer, and polished for CCSEM analysis. All fractions are weighted. The CCSEM analyses were conducted using the standard routines developed at the Department of Geological Mapping at GEUS. About 600 grains were analysed in each sample.

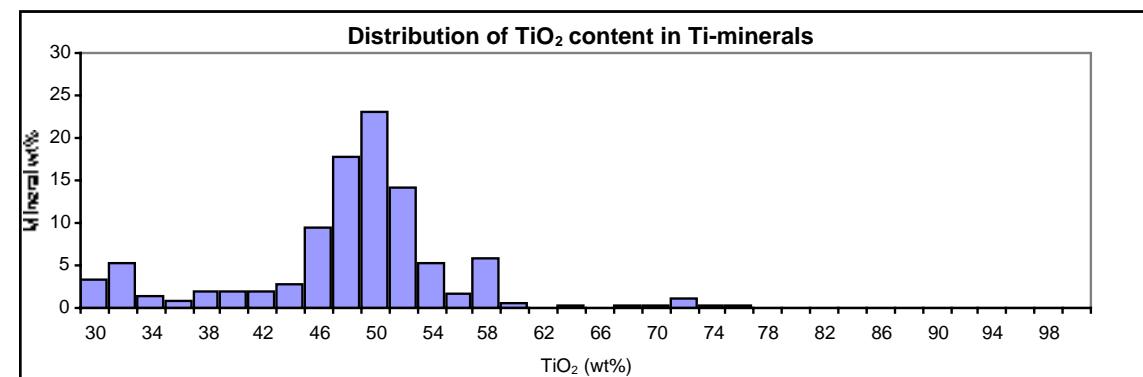

For bulk XRF analysis, a 30 grammes split was crushed in tungsten-carbide mortar. About 2 grammes of the powder was pressed into pellets and run by a PANalytical MagiX PRO spectrometer at the Geological Institute, University of Copenhagen. The reported major element analyses have been calibrated against a series of sediment samples run by the major element XRF laboratory at GEUS on fused glass discs. XRF data on all 40 samples will be reported in 2005 Madagascar Report to DuPont.

5. Results and discussion

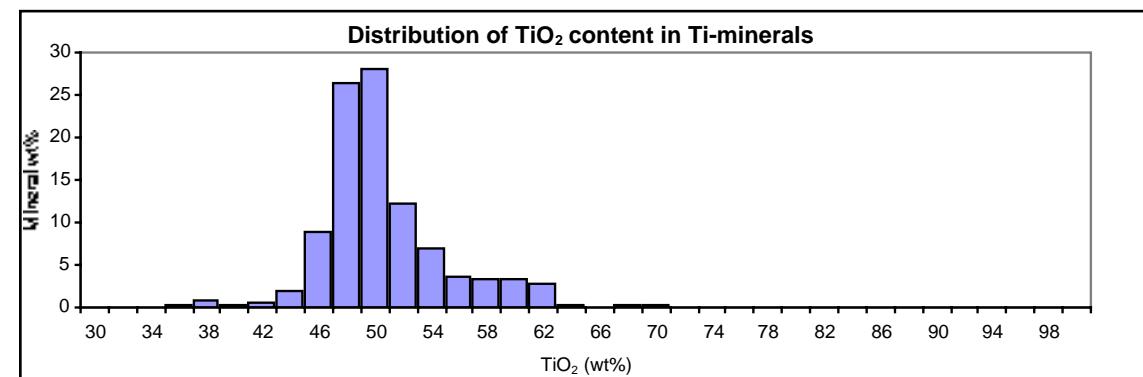

5.1 Distribution of TiO₂ in titanium-bearing minerals

In short, CCSEM analyses show that 13 of the samples were found to have ilmenite with average TiO₂ between 54.6 and 57.9 wt. %, and these will in the following be referred to as 'intermediate-Ti' samples. Five samples were found to have ilmenite with average TiO₂ > 60 wt. % (60.5 - 64 wt. %), and these samples will be referred to as 'high-Ti' samples. The remaining 15 samples have TiO₂ in average ilmenite of between 50 and 53.6 wt. % and will be referred to as 'low-Ti' samples.

The five high-Ti samples come from a relatively large stretch of coast from north of St. Luce, over some 80km towards the south and a bit west of Fort Dauphin. Most of the intermediate-Ti samples come from the same region, but extend further 60 km to the north along the coast towards Manambondro. The remaining samples, from around Manambondro and along the southwest coast from Fort Dauphin belong to the low-Ti group. Exceptions to this is a series of samples (65, 66, 69, and 71) that all come from a region around the town of Androka, and which have elevated Ti in average ilmenite.

2000773 Average TiO₂ in ilmenite: 51.36

2000775 Average TiO₂ in ilmenite: 50.05

2000777 Average TiO₂ in ilmenite: 53.72

In Fig. 3 is presented a summary of the individual samples in terms of the distribution of TiO₂ in Ti minerals. The two samples 39 and 40 have low average TiO₂ in ilmenite, and the ilmenite found in these samples probably comes from the Mesozoic volcanic rocks exposed along the east coast of Madagascar and from the extensive belt of Precambrian orthogneisses, including charnockites, which forms the basement to the volcanic cover. A similar distribution of TiO₂ is seen for sample 42, from the Isandra river, which drains part of the same orthogneiss lithologies. The picture changes as the sample locations move south. Samples 41 to 50 (excluding the high-Ti sample 49) are similar in displaying a more complex distribution of TiO₂ in titanium minerals. Several of these samples have elevated TiO₂ in ilmenite (up to 56.6 wt. %), and they all show a bimodal distribution of TiO₂ in ilmenite, with a distinct group of low-Ti ilmenite, with TiO₂ peaking around 50 or 52 wt. % and a less well defined group of ilmenite with elevated TiO₂ from 55 to >70 wt. % TiO₂. It is interesting to note that the low-TiO₂ population ilmenite in the samples apparently changes so that

samples 39, 40, 42, 44, 46, 48, and 50 have a low TiO_2 ilmenite population with TiO_2 of around 50 wt. %, while the samples 41, 43, 45, and 47 have a low TiO_2 ilmenite population with TiO_2 of around 52 wt. %. This suggests that there may be at least three major sources for ilmenite in these sediment samples, one with around 50 and one with around 52 wt. % TiO_2 , and one of altered ilmenite with $\text{TiO}_2 > 58$ wt. %. The origin of the altered ilmenite could be either of the low-Ti ilmenite populations, but the three types of ilmenite must reside in different reservoirs, since the samples show clear bimodal distributions. This is in contrast to intermediate-Ti samples from Kerala beaches in India, where there exists a gradual, skewed normal distribution in TiO_2 of ilmenite in the samples (see Bernstein, 2003, Fig. 3 therein, samples 2000248 and 250).

The five high-Ti samples (49, 51, 52, 53, and 55) contain very few ilmenite grains with low TiO_2 . In fact, most of the samples contain no unaltered ilmenite grains ($\text{TiO}_2 < 52.6$ wt. %, which is the stoichiometric value), and sample 55, which have the highest TiO_2 of 64 wt. % for average ilmenite, is remarkable in having >90 % of the ilmenite grains with between 60 and 70 wt. % TiO_2 . This is a much narrower compositional range for ilmenite than found in high Ti samples from Kerala beaches. Sample 55 is found some 7km inland from the coast in what appears to be palaeobeach sediments, perhaps raised beaches. The two samples 54 and 56 found at the coast, about 10km from sample 55, contain a low-Ti ilmenite component, with TiO_2 at around 50-52 wt. %, and thus have lower average TiO_2 of 57-58 wt. %. These two samples, however, contain relatively few ilmenite grains in the range 64-68 wt. % TiO_2 , which is the range at which sample 55 contains most ilmenite grains. The most likely explanation for this must be that ilmenite in sample 55 has been altered to high purity *in situ*. Alternatively, but less likely, is ilmenite in sample 55 derived from a different source than ilmenite in the nearby sample 54 and 56.

From about 30km west of samples 55-56, the lithologies change into sedimentary basins of various ages. Distribution of TiO_2 in ilmenite changes accordingly, and TiO_2 in average ilmenite is low in the samples 57-64. There is little difference in the distribution of TiO_2 in Ti minerals and, more specifically, in ilmenite between these samples, although samples 57, 58, and 61 all come from inland sedimentary basins, and samples 59, 63, and 64 are from beaches. From 30km west of Cap St. Marie, the distribution of TiO_2 in Ti minerals changes again, heralded by the intermediate-Ti samples 65 and 66, which mostly contain altered ilmenite in the range 52-60 wt. % TiO_2 . These two samples come from an area of flat sandy plains within the sedimentary basin. Continuing towards the northwest, the TiO_2 distribution of Ti minerals becomes complex. All samples contain a relatively high fraction of altered ilmenite ($\text{TiO}_2 > 52.6$ wt. %), and most also contain a significant proportion of rutile, which is nearly absent in samples from the samples east of sample 61. Sample 68 is particularly interesting, because it contains two distinct groups of ilmenite. One group of altered ilmenite with unusually low TiO_2 of 44-52 wt. %, and one group with TiO_2 mainly between 58 and 70 wt. % TiO_2 . There is a clear compositional gap between the two groups. It is not possible to determine whether the ilmenite is altered *in situ*, and the low TiO_2 ilmenite simply is resistant to the alteration processes, or, whether the high TiO_2 ilmenite is derived from a separate source, which already has undergone alteration. Due to the present arid climate in southeastern Madagascar, the latter explanation is favoured.

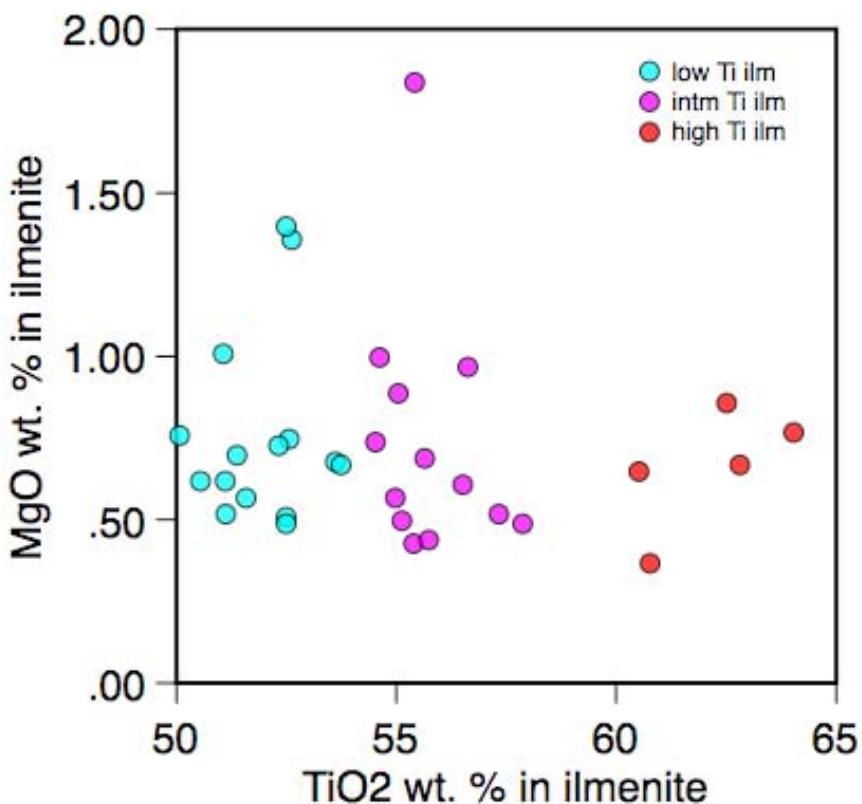

Figure 4. *MgO* versus *TiO₂* in average ilmenite from southern Madagascar.

5.2 Ilmenite chemistry

In contrast to the study from India (Bernstein, 2003), there appears to be no correlation between average MgO in ilmenite and the average TiO₂ (Fig. 4). There is a large variation in MgO in ilmenite for the high-Ti samples (0.4 to 0.9 wt. %) and similarly large variations for MgO in the low- and intermediate-Ti samples. Manganese, on the other hand, yields considerable more information. In Fig. 5, it appears that samples from the eastern part of southern Madagascar (samples 39-56), which all come from areas adjacent to the A1-A2 schists of the khondalite belt (Fig. 1), have low MnO (0.4-0.6 wt. %), except sample 39. The anomalously high MnO of sample 39 is best explained by the fact that ilmenite at this sampling site must be derived mainly from the Cretaceous volcanics. Samples from western Madagascar (samples 57 to 78) have significantly higher MnO, namely 0.75 to 0.9 wt. %. Exceptions to this is one sample (71) with 1.3 wt. % MnO, and two samples (61 and 68) which have MnO of around 0.6 wt. %. It is here of particular interest to note that one of

these two samples with low MnO is sample 68, which contains a high-Ti ilmenite population.

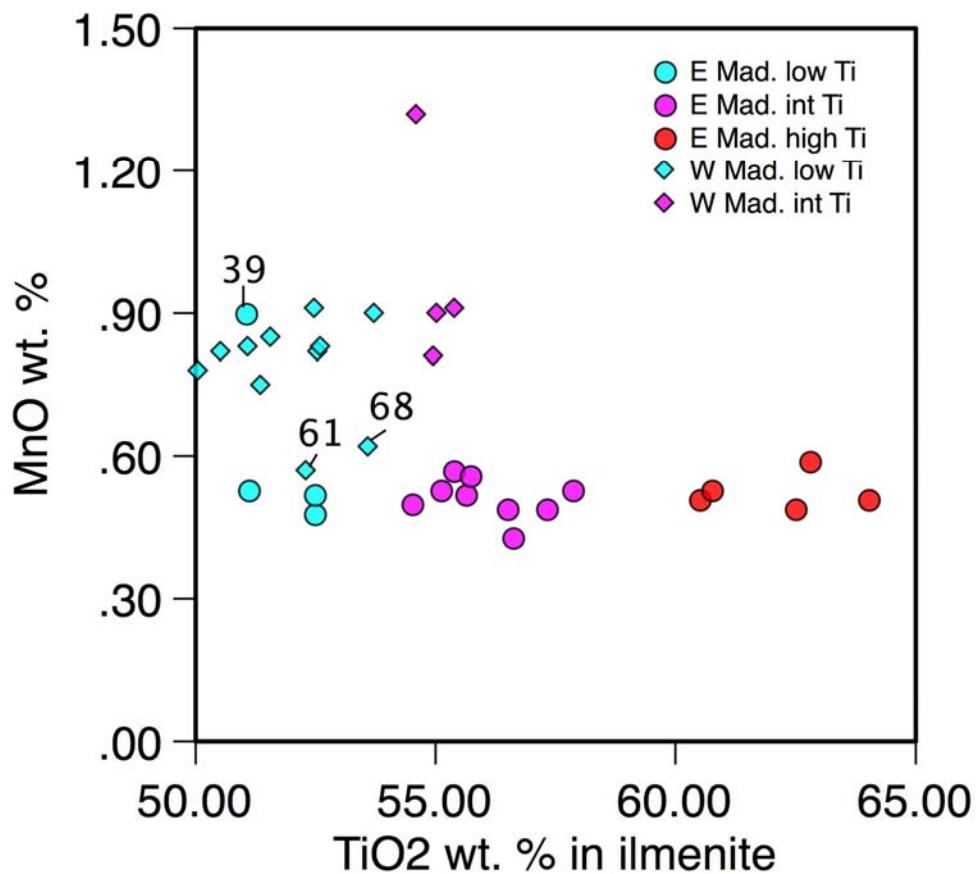

Figure 5. *MnO* versus *TiO₂* in average ilmenite from Madagascar. Circles represent samples from eastern Madagascar (east of sample 57), while diamonds represent samples from western Madagascar (west of sample 57). The colours refer to *TiO₂* contents in average ilmenite (see legend).

5.3 Garnet chemistry

Average garnet compositions from the 33 samples are presented in Fig. 6 in terms of the three ideal end-member components. The samples from eastern Madagascar form a coherent group with uniformly low grossular components of 2.1 - 4.0%, and pyrope contents of between 21 and 32.5%. Sample 39 lies the high pyrope end of the group. Most samples from western Madagascar have elevated contents of the grossular component, with values that generally lie between 6 and 12 %. There are some exceptions, namely samples 57, 58, 59, 64, and 65, which all have between 4 and 5 % grossular component in their average

garnet. Of these, the three samples 57, 58, and 59 represent the area at the eastern edge of the sedimentary basin that occupies the western Madagascar (Fig. 2). It is thus likely that the sediment represented by these samples receive a substantial amount of garnets from the schists which also feed the sediments sampled in eastern Madagascar. Manganese content in the garnets from eastern Madagascar is mainly low, in particular for the samples that also contain high-Ti ilmenite (Fig. 7). Due to the low contents of garnets in high-Ti samples, only two samples from this group are represented in this figure, but they plot at the lower end of the MnO group, with 0.45–0.55 wt. % MnO in average garnet. Garnets from western Madagascar either have higher MnO or higher grossular components and therefore are distinctly different from garnets from the eastern Madagascar samples. Three samples have both low MnO and low grossular garnets, and these are, again, samples 57, 59, and 65.

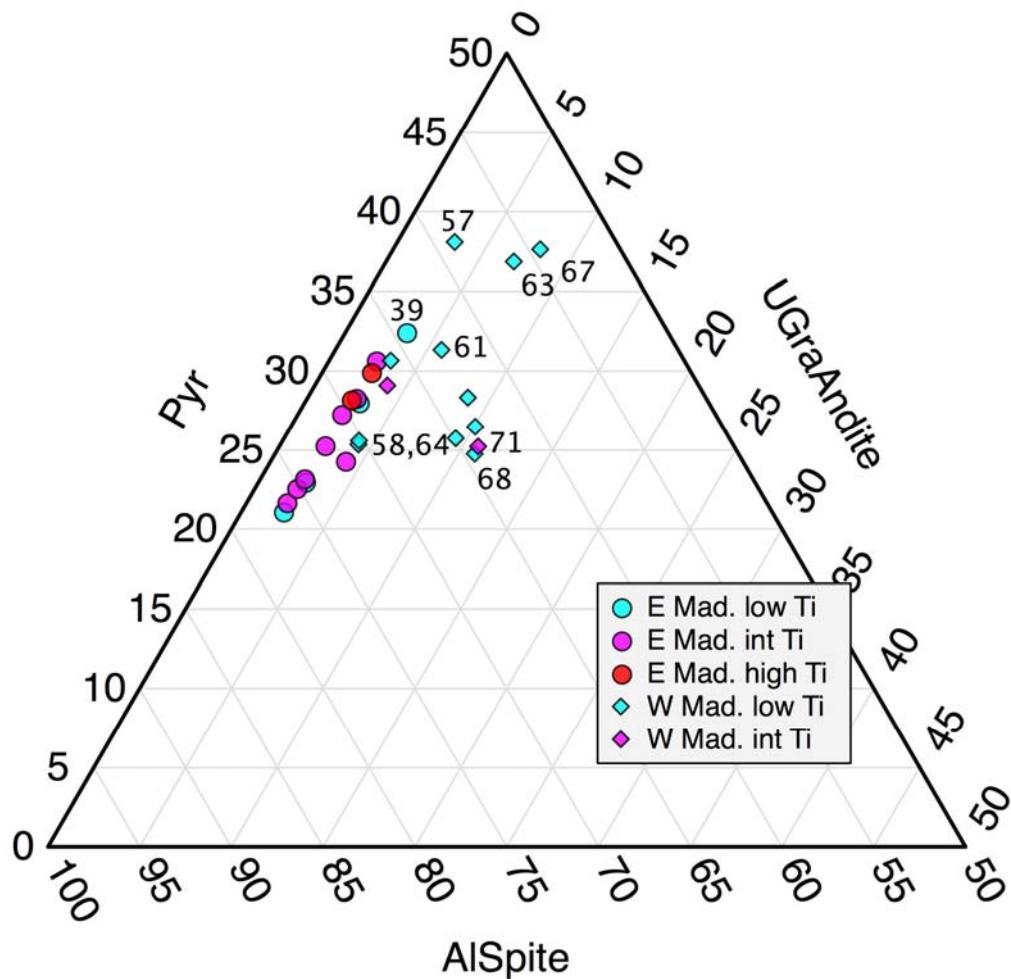

Figure 6. Composition of average garnet in terms of the ideal end member components Pyrope-Almandine+Spessartine-Ca-garnets (Uvarovite+Grossular+Andradite).

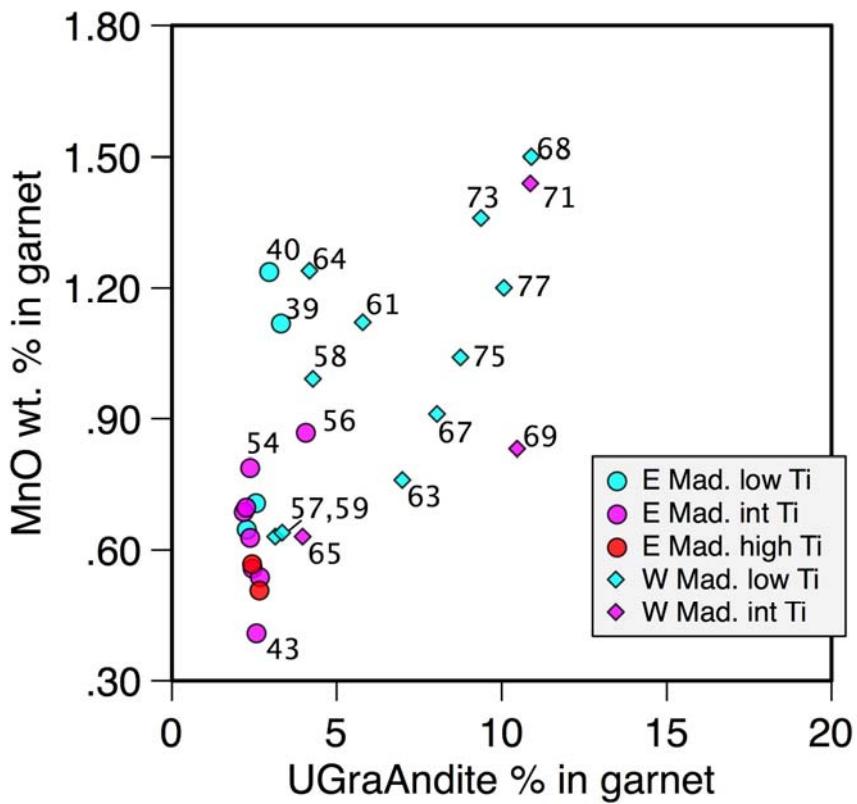

Figure 7. *MnO versus Ca-garnet component in average garnets from Madagascar.*

5.4 Compositional distribution of garnets

Individual garnet analyses for selected samples are presented in Fig. 8. For the northernmost sample 39, garnets show a relatively restricted compositional range, with pyrope values between ca. 25 and 40%. Samples from the coast south of sample 39 (samples 40 to 56) all show larger ranges in pyrope components, regardless of the Ti content of the average ilmenites. In Fig. 8 are presented four samples from this coast stretch, including the two intermediate-Ti samples 41, and 47, and the two high-Ti samples 49, and 51. For all four samples the range in pyrope is between ca. 15 and 37% (the range in sample 51 is smaller, perhaps because of the smaller population of garnet grains). For curiously, it is worth noting that all these 4 samples contain a small population of garnets with about 40-44 % pyrope - and separated from the main body of garnet data. The high average pyrope garnet in samples 39, likely suggests derivation from the Archaean-Neoproterozoic gneiss terrain that extends to the north and west underneath the Cretaceous volcanic cover (Fig. 2).

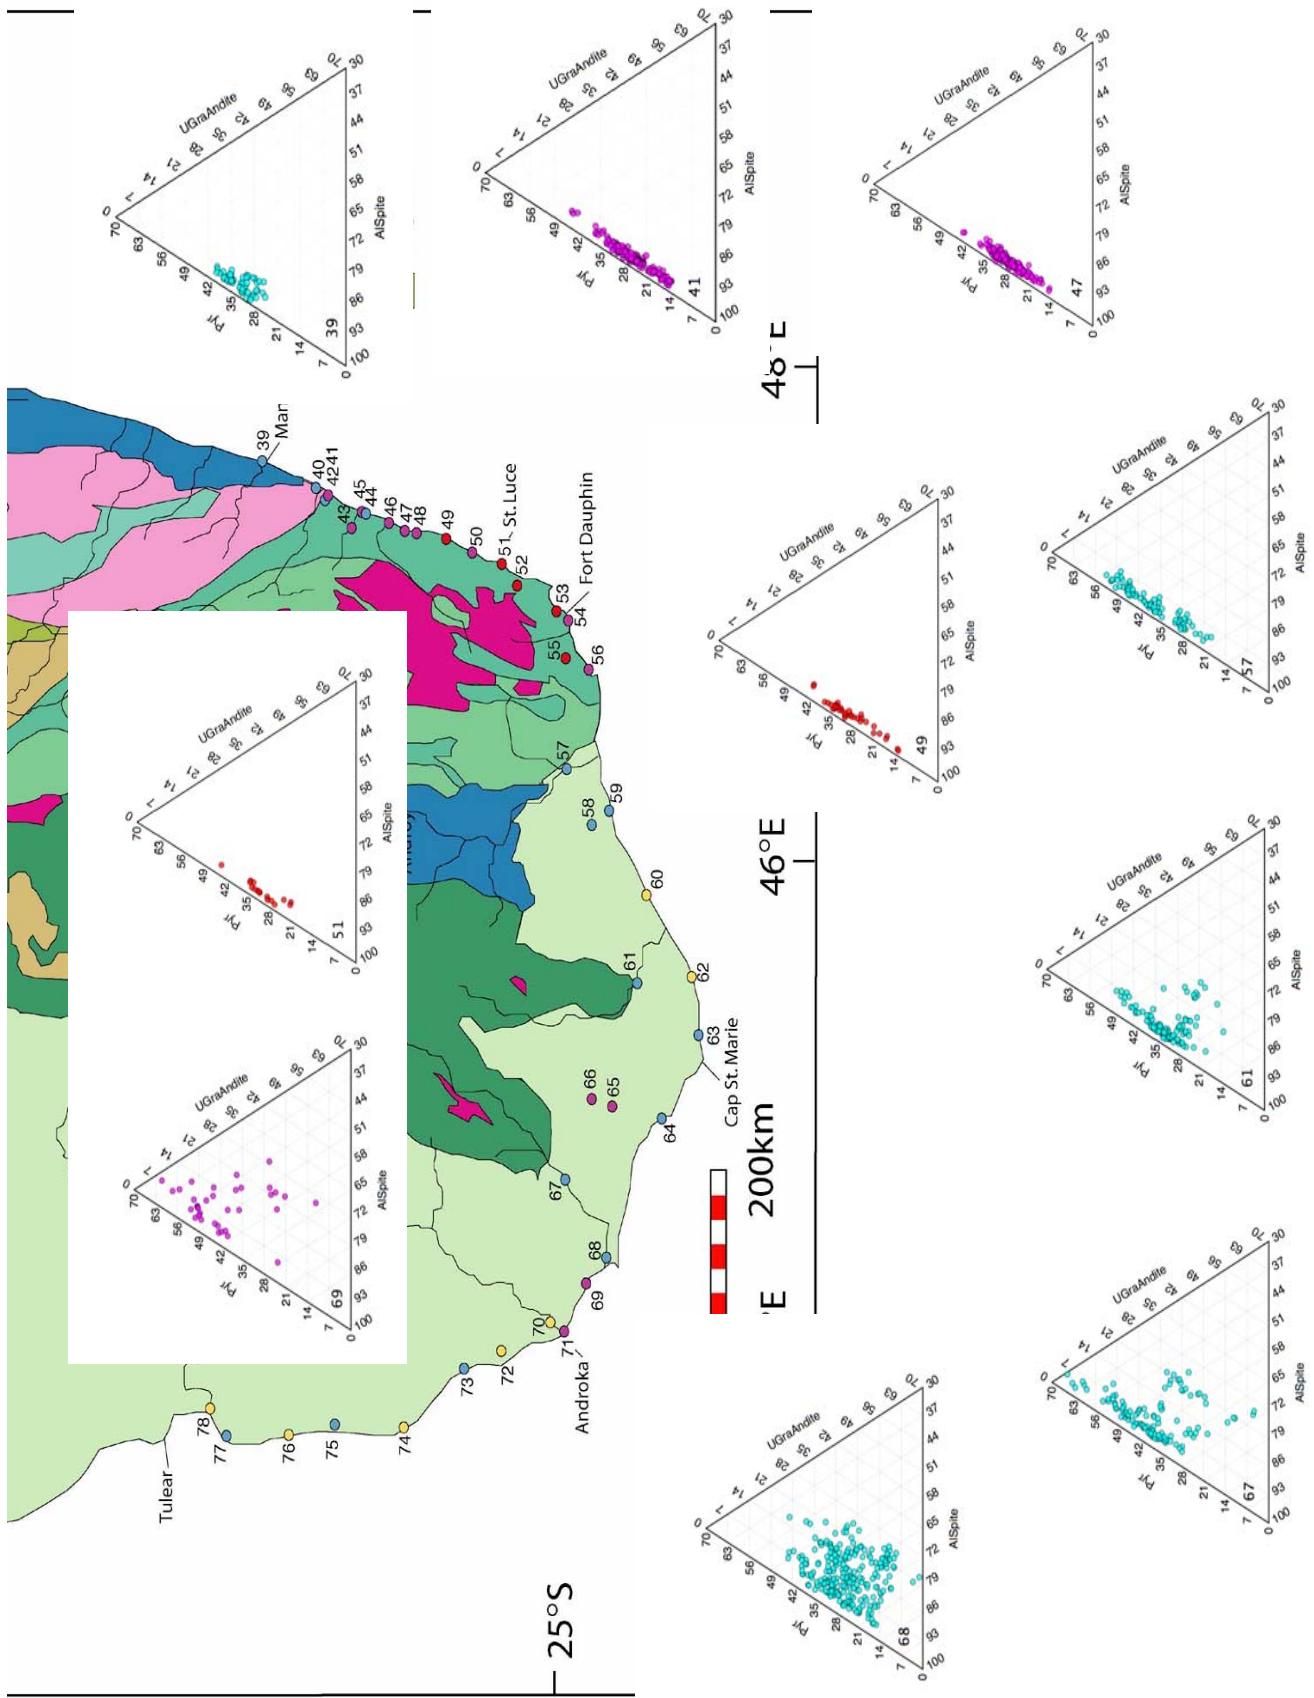

Figure 8. Individual garnet compositions for a series of selected samples from Madagascar. Sample numbers are given in lower left corner of the garnet triangles. Colour of symbols refer to high-Ti samples (red), intermediate-Ti samples (purple), and low-Ti samples (blue).

The sampled areas west of sample 56, referred to as western Madagascar, yield garnets with distinctly different compositions, compared to the samples 39-56. The first samples west of 56 is 57, and in this sample there is still quite a few garnets with the low grossular components, but a new group enters the scene, with pyrope contents to 53%. Sample 59 is similar to 57, showing that some garnets are still derived from the A1-A2 schists. In the samples 61 and 64, a low grossular garnet population still occurs, but from west of 64, all analysed garnets contain more than 4% grossular component, and most are considerably higher, with values up to 28%. In general the variations in the ideal garnet end-member components are large, within the garnets from individual samples. This is not surprising since the sediment samples come from a sedimentary basin which have been active over a long time span of nearly half a billion years, and thus is likely to represent material from a variety of source rocks.

5.5 Comparison with India sediment samples

Comparing the ilmenite compositions from Madagascar and India sediment samples (Fig. 9) shows that there is a very good agreement in terms of MnO-TiO₂ systematics between the two countries. All India and all Madagascar samples with average ilmenite higher than 56 wt. % TiO₂ have MnO between 0.4 and 0.6 wt. %. Sediments from north Kerala, i. e. outside the beaches that receive material from the khondalite belt, have MnO in average ilmenite from 0.8 to 1.6 wt. %. A similar behavior is found in samples from western Madagascar, as discussed above. Comparing the garnet compositions from India (Figs. 10 and 11) and Madagascar shows that there is extremely good agreement between high-Ti sample from the two countries. This not only confirms the suggestion of granulite facies metasediments from the khondalite belts to be the source rocks for the high grade ilmenite, but it also attests to a common origin for the belts of metasediment in India and Madagascar.

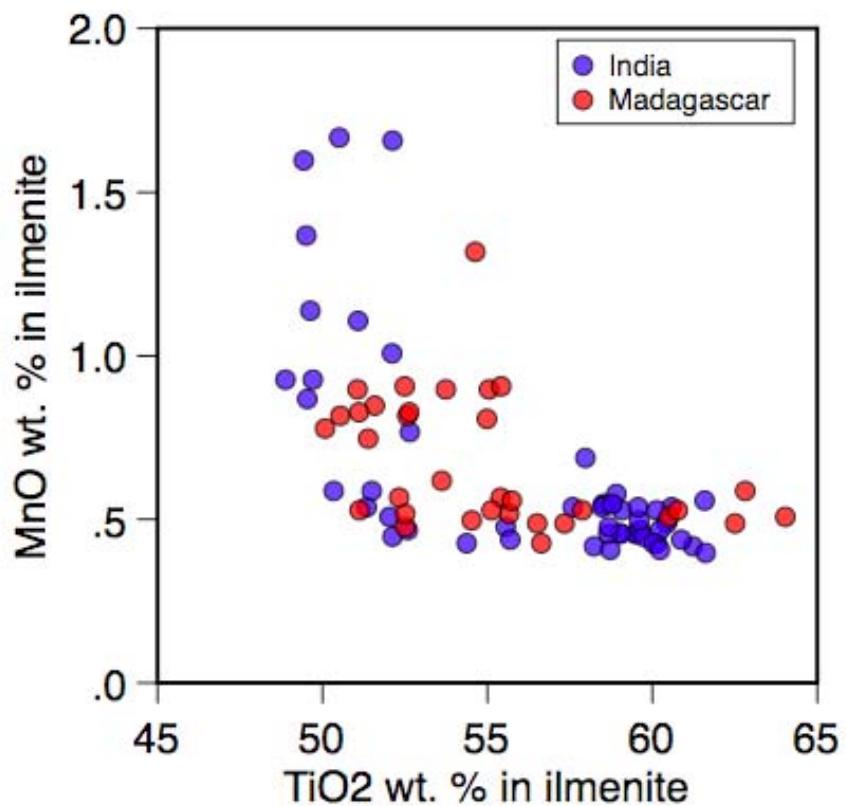

Figure 9. Composition of average ilmenite in sediments from India (data from Stendal et al., 2003; and Bernstein, 2003), compared to ilmenite in sediments from Madagascar (this study). Note the uniform, and low MnO of ilmenite in all samples with average ilmenite having TiO₂>56 wt. %.

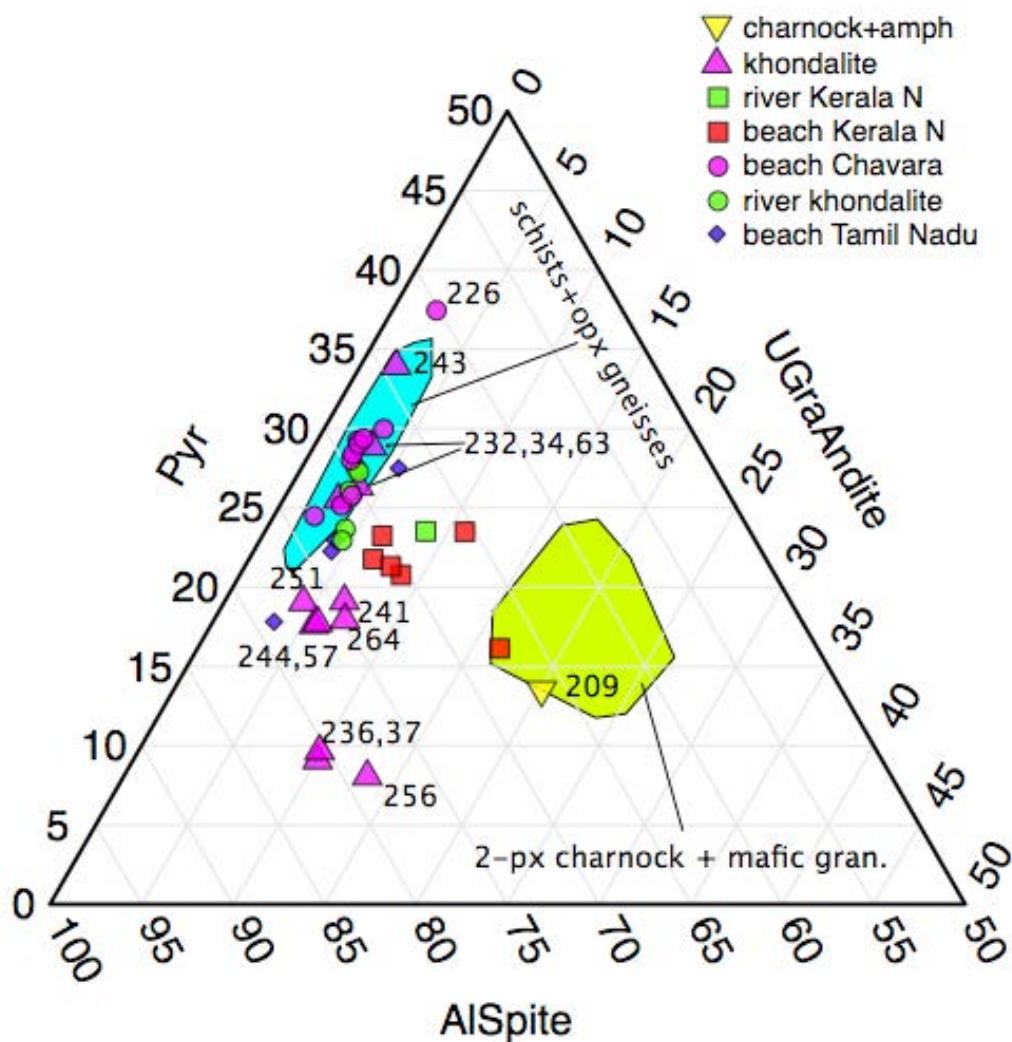

Figure 10. Composition of average garnets from sediments and rocks from southern India. Compare garnet compositions from Indian high-Ti samples (purple circles) with garnets from high-Ti samples from Madagascar (Fig. 6). (Data and figure from Bernstein, 2004).

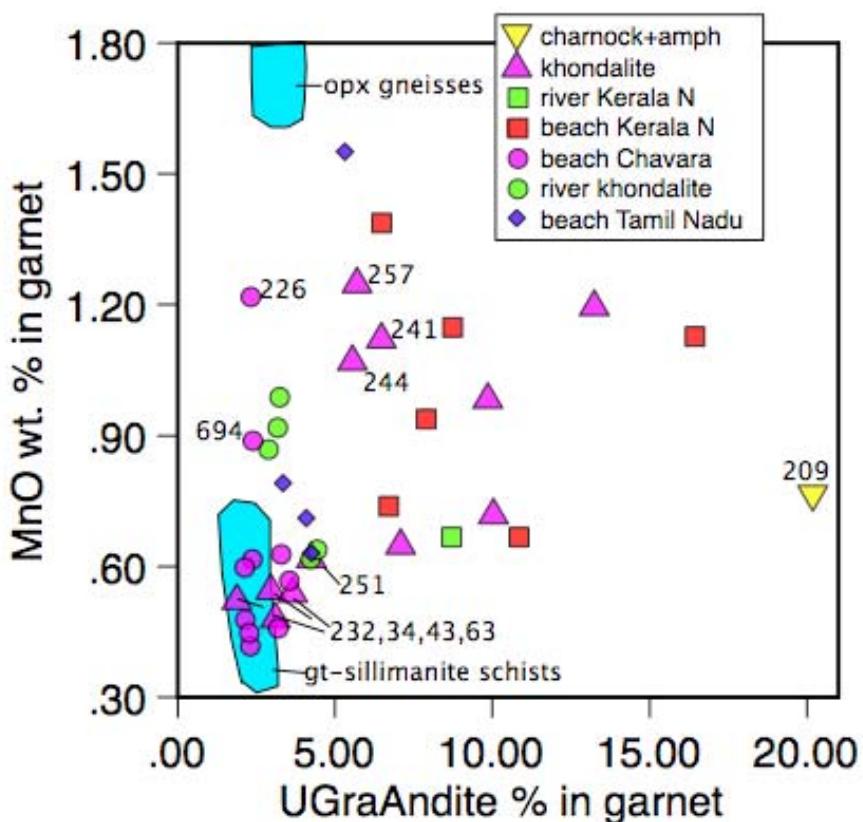

Figure 11. Composition of average garnets from sediments and rock from southern India. Compare garnet compositions from Indian high-Ti samples (purple circles) with garnets from high-Ti samples from Madagascar (Fig. 7). (Data and figure from Bernstein, 2004).

6. Future developments

The recognition of high-Ti ilmenite in several sediment samples from southern Madagascar indicates a high potential for economic deposits of ilmenite. The stretch of coast with high-grade ilmenite is in length and grade comparable to that of the Chavara deposits in Kerala State, southern India. It is recommended that the outline of the potential deposits from around Fort Dauphin and some 100km north is refined by further sampling of sediments. Since the potential source rocks outcrop close to the coast, a set of rock samples should also be collected, which together with sediment samples should provide further insight into the ilmenite alteration processes.

Likewise, the area around and east of Androka (Fig. 2) in western Madagascar should also be sampled to test the potential of the samples which have indicated some intermediate-Ti ilmenite deposits.

8. Appendix 1

Madagascar field diary.

Sediment sampling programme 17/5-14/6-2004

Geologist Rasmus Christensen

General remarks.

This field diary is written as a rough itenary of the day to day travels and activities. Samples are listed and described on the date they were taken. Place names in the sample descriptions refer to the nearest settlement on the 1:100.000 map for quick identification of the sample sites. All GPS positions are taken in WGS 84 on the UTM net.

17/5-2004

Arrived in Antananarivo international airport. Met with guide (prearranged through personal contacts)

18/5-2004

Reconnaissance day. Visits to a variety of ministries in order to inquire about the necessary permits.

19/5-2004

Acquired a prospecting license for the southern part of Madagascar at "Bureau central du cadastre minier"

20/5-2004

Route planning, buying supplies and booking transport.

21/5-2004

Taxibrousse from Antananarivo to Fianarantsoa. Papers stamped at the regional mining office in Fianarantsoa.

22/5-2004

Transport day. Train from Fianarantsoa to Manakara

23/5-2004

Transport day. Taxibrousse from Manakara to Farafangana and then from Farafangana to Vangaindrano.

24/5-2004

Taxibrousse from Vangaindrano to Manambondro.

Andriambe river app. 10 km inland at Mororoy village. Fine grained river sediment.

27/5-2004

Went down Andriambe river in piroque. Got a ride with lobster buyers to Manantenina. The geology in this region is characterized by a steep foreshore, app. 50 m of beach and coast parallel stabilized coastal dunefields up to 1 km wide. Behind the dunefields a rolling grassy plain with numerous gullies stretches back to the mountain range. The plain is made up from deeply eroded bedrock with a thin cover of red soil. Small deposits of Aeolian sand can be found as far back as 5-6 km from the coast, but usually quite small and with a maximum thickness of 1-2 m.

Sample: Mad04-06 GEUS 2000744

Pos.

S 24 11.349

E 047 23.952

App. 1 km south of the mouth of Andriambe river. Scattered outcrops of bedrock in the surf. 5 m erosional coastal cliff. Material appears to be from old beach ridges. Garnet makes up app. 50% of the heavies.

Sample: Mad04-07 GEUS 2000745

Small sample of heavies sorted and concentrated on the beach. 200 m north of Mad04-06.

28/5-2004

Rented ex-army truck and drove from Manantenina to Vatomirindry with stops on the way to collect samples. The road runs between 2-7 km from the coast.

Sample: Mad04-08 GEUS 2000746

Pos.

S 24 18.761

E 047 20.241

Ampasamosay. Low stabilized coastal dunes. Dunefield app. 1,2 km wide with a short transition inland where eroded bedrock dominates.

Sample: Mad04-09 GEUS 2000747

Pos.

S 24 23.745

E 047 18.666

Esama. Stabilized coastal dunefield. Very swampy area with coast-parallel small rivers running behind the dunefield and deeply eroded bedrock crops out in numerous places.

Sample: Mad04-10 GEUS 2000748

Pos.

S 24 26.007

E 047 18.197

Ankaramany. Large stabilized coastal dune.

Sample: Mad04-11 GEUS 2000749

Pos.

S 24 32.113

E 047 16.442

Manambato. Inlandside of coastal dunefield app. 700 m from the sea.

29/5-2004

By truck from Vatomirindry to Fort Dauphin.

Sample: Mad04-12 GEUS 2000750

Pos.

S 24 40.855

E 047 12.770

Vatomirindry. Possibly old beach ridge as sediment is coarser than the samples from the dunes, but difficult to establish on the basis of the morphology. Width of deposit app. 300 m.

Sample: Mad04-13 GEUS 2000751

Pos.

S 24 46.751

E 047 11.770

Saint Luce. Active dunes (100 m wide, 10 m asl.) composed mainly of shell fragments.

Sample collected in flat area behind the active dunes, old beach?

30/5-2004

Day of rest in Fort Dauphin.

31/5-2004

Rented car in order to collect samples in the Fort Dauphin area.

Sample: Mad04-14 GEUS 2000752

Pos.

S 24 50.661

E 047 06.279

Belavenoka. Sediment from raised beach ridge 4-5 km inland from recent coast.

Sample: Mad04-15 GEUS 2000753

Pos.

S 25 00.210

E 046 58.982

3 km north of Fort Dauphin. Very steep active dune (angle of repose). App. 40 m asl.

1/6-2004

Rented 4wd with driver for the trip Fort Dauphin to Toliare. This day Fort Dauphin to Ambo-sary.

Sample: Mad04-16 GEUS 2000754

Pos.

S 25 04.003

E 046 56.238

Ambinambe. The inland side of steep partially active coastal dune. Heavies visible in wind ripples. Behind the dune lots of bedrock outcrops.

Sample: Mad04-17 GEUS 2000755

Pos.

S 25 03.004

E 046 48.394

Manambaro. Gently sloping sand plain with small-scale dunes. Dug sample holes in quite a few places but not a lot of visible heavies.

Sample: Mad04-18 GEUS 2000756

Pos.

S 25 08.387

E 046 46.536

Italy. App. 300 m wide active dunefield between the sea and a large bedrock outcrop. Some shell fragments in the sand.

2/6-2004

Ambosary to Tsiombe

Sample: Mad04-19 GEUS 2000757

Pos.

S 25 02.833

E 046 22.748

Mandrare river at Ambosary. Sample from large pointbarre in the partially dry riverbed. Well developed cross stratification with drapings of heavies. Fine-coarse sand.

Sample: Mad04-20 GEUS 2000758

Pos.

S 25 13.522

E 046 11.998

Maroaloka. Coastal dunefield app. 250 m wide.

Sample: Mad04-21 GEUS 2000759

Pos.

S 25 08.420

E 046 06.183

4 km north of Ambovombe. Inland sedimentary basin. Difficult area to sample as a cementlike crust has formed a few cm below the surface due to the arid nature of the region. Flat to gently rolling plain.

Sample: Mad04-22 GEUS 2000760

Pos.

S 25 22.593

E 045 50.590

Katoala Tannanbao. Very large active coastal dune complex. 700-800 m wide and 40-50 m asl. Some shell fragments in the sand.

3/6-2004

Tsiombe to Beloha. Very arid region. Very little relief.

Sample: Mad04-23 GEUS 2000761

Pos.

S 25 19.197

E 045 28.976

Manambovo river at Tsiombe. Dry river bed. This river only carries water a few months a year. Coarsegrained sand dominates.

Sample: Mad04-24 GEUS 2000762

Pos.

S 25 34.163

E 045 31.669

Faux Cap. 300 m wide active coastal dunefield. Finegrained sand with some shell fragments.

Sample: Mad04-25 GEUS 2000763

Pos.

S 25 34.753

E 045 17.801

Ankaratravitra. Sand plain gently rising inland. Large active dune field along the coast. Fine-coarse grained sand dominates the plain.

Sample: Mad04-26 GEUS 2000764

Pos.

S 25 25.192

E 044 56.338

Lavanono. Coastal dunes. Lots of heavies on the beach and in the dunesand.

Sample: Mad04-27 GEUS 2000765

Pos.

S 25 13.866

E 045 01.208

1 km north of Barabay. Flat sandy plain. Some outcropping bedrock.

Sample: Mad04-28 GEUS 2000766

Pos.

S 25 09.930

E 045 04.311

1 km northeast of Beloha. Flat sand plain. Fine grained sand.

4/6-2004

Beloha to Androka.

Sample: Mad04-29 GEUS 2000767

Pos.

S 25 03.168

E 044 40.870

Menarandra river at Ampotaka. Sample taken from the dry river bed. Lots of heavies. Dominating grainsize is fine-coarse grained sand with some clay drapes and few walnut size stones. River bed is 500-600 m wide.

Sample: Mad04-30 GEUS 2000768

Pos.

S 25 12.528

E 044 27.008

Lahitsitely. Looks like old dunefield 5-6 km inland. Gently undulating landscape with very old vegetation.

Sample: Mad04-31 GEUS 2000769

Pos.

S 25 08.746

E 044 18.279

Ampalaza. Partly stabilized coastal dunefield. Heavies visible in wind ripples. Apparently lots of heavies in this region (from sites Mad04-31 to Mad04-35).

Sample: Mad04-32 GEUS 2000770

Pos.

S 24 58.066

E 044 08.449

Ilinta river at Saodona. Dry river bed. Medium-coarse sand dominates but also few clay drapes visible.

5/6-2004

Androka to Anakao

Sample: Mad04-33 GEUS 2000771

Pos.

S 25 01.843

E 044 04.402

Androka. Very large active coastal dune complex. Dunes stretching app. 1 km inland.

Sample: Mad04-34 GEUS 2000772

Pos.

S 24 46.802

E 043 58.298

Nisoa. Gently undulating sand plain. Fine-medium sand with visible garnet + other heavies.

Sample: Mad04-35 GEUS 2000773

Pos.

S 24 38.460

E 043 56.575

Lavavolo. Coastal dune field. Lots of garnet in this region.

Sample: Mad04-36 GEUS 2000774

Pos.

S 24 21.627

E 043 40.852

Lanivato. Coastal dunes. Sand somewhat mixed with shell fragments.

Sample: Mad04-37 GEUS 2000775

Pos.

S 24 05.587

E 043 41.891

Efoetse. Sand plain behind the coastal dunes. Sand does not seem to be well sorted, but that is typical of the sand plain.

Sample: Mad04-38 GEUS 2000776

Pos.

S 23 54.198

E 043 40.602

Beloha. Low coastal dunes. Fine grained sand. Heavies visible in the wind ribbles.

Sample: Mad04-39 GEUS 2000777

Pos.

S 23 09.094

E 043 39.171

Anakao. Low coastal dunes. Fine-coarse sand (seems to be quite unsorted for coastal dunes) few shell fragments.

6/6-2004

Anakao to Toliare

Sample: Mad04-40 GEUS 2000778

Pos.

S 23 32.115

E 044 19.312

Onilahy river at Tongobory. River sediments. Medium-coarse sand.

7/6-2004

Day spent at various offices in Toliare. Mayors office and the regional office for the ministry of mining.

8/6-2004

Rest day

9/6-2004

Domestic flight back to Antananarivo and straight to the ministry to apply for an export license.

10/6-2004

Another day at the offices in the ministry.

11/6-2004

Got the last stamps for the export permit.

12/6-2004

Rest day

13/6-2004

Packing samples and equipment. Off to the airport and back to Denmark with the samples!!

9. Appendix 2

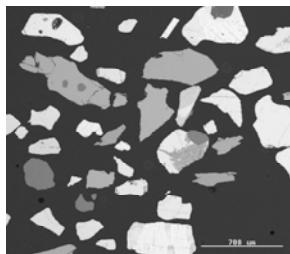

CCSEM report sheets for 33 sediment samples 2000739-2000777.
